

Abu Bakar & Hamza' Project

Campus Notes Intro:

CampusNotes is a university notes sharing web app built for students to find, download, and upload study materials in one place. Students can register and log in, browse notes and past papers by semester and subject, search documents, and upload PDFs for their classmates. The app is designed as a simple, organized digital library to help students share knowledge and prepare for exams more easily.

Github Repo: <https://github.com/AbubakarTechy/NotesApp/>

Vercel Live: <https://notes-app-nine-liard.vercel.app/>

(I am working hard on to deploy for the whole university to make it product)

Things I learned:

Google Auth Login Guide: https://chatgpt.com/s/t_6a2ea4e031ac81919238fc07439a3b3d

Pricing plan Guide: <https://chatgpt.com/share/6a2f2fd6-4ce4-83ee-8789-76dec51b5c26>

Cloudinary Set: <https://chatgpt.com/share/6a2f3245-c4c8-83ee-b84d-dd77c4f16383>

1. Design Find

Top level engineers don't start to code on an idea without a plan. They made plans, sketches, plans or prototypes on page to make architecture of their app. So, including me to top level eng category I started to find design for my app on Figma. I searched and explored 10 to 15 designs and did not love them.

2. Sketch the design

Due to a short time, I sketched the design on page and layout it. Use my mind that in home page what to show and so on. It helps to visualize my app that it will look at the end like this.

4. Prompt Engineering

I developed the project myself and used Cursor AI as a helper during development. Cursor assisted me with debugging errors, explaining code, suggesting improvements, and speeding up repetitive tasks. However, the project design, features, logic, and implementation decisions were created and managed by me. Using Cursor helped me solve problems faster and learn better development practices throughout the project.

5. Map design with my sketch

After creating a rough sketch on paper, I compared it with the selected design ideas and started building the actual interface. I converted my sketch into web pages and adjusted the layout so that it matched my original plan. This helped me maintain a clear structure throughout development.

5. Organize fronted

I organized the frontend by creating separate folders for pages, components, and reusable UI elements. Each page was divided into smaller components to keep the code clean and easy to maintain. This structure made future updates and debugging simpler.

6. Organize Backend

I organized the backend by separating routes, controllers, models, and middleware into different folders. This modular structure improved code readability and made it easier to manage authentication, file uploads, and database operations.

7. Filter Issue resolved

While developing the notes browsing feature, I faced issues with filtering notes by semester and subject. After debugging the logic and testing different cases, I fixed the filtering system so that students can quickly find the notes they need.

8. Paid Plan Logic

To support premium users, I implemented a paid plan system. I designed rules for free and premium accounts, including download limits and feature access. I researched different pricing models and used ChatGPT as a guide while implementing the logic.

9. Cloudanary for storage

I learned how to use Cloudinary for cloud file storage. Instead of storing PDF files directly on the server, uploaded files are stored on Cloudinary and their URLs are saved in the database. This improved file management and scalability.

10. Google Auth Add

I implemented Google Authentication to provide a quick and secure login method. I learned the setup process using Google Cloud Console and integrated Google Sign-In into the application, allowing users to create accounts and log in with a single click.

I go to Google cloud and learn Google Auth through gpt and DONE
